

Negating interfacial impedance in garnet-based solid-state Li metal batteries

Is lithium metal/Garnet interfacial impedance reduced at room temperature?

A significant decrease of interfacial impedance, from $1,710 \, \Omega \cdot \text{cm}^2$ to $1 \, \Omega \cdot \text{cm}^2$, was observed at room temperature, effectively negating the lithium metal/garnet interfacial impedance.

Can mechanical design reduce lithium dendrite formation in solid-state lithium batteries?

Mechanical Design Approaches for Dendrite Suppression In addition to chemical and interfacial modifications, mechanical design strategies are increasingly recognized as effective means to mitigate lithium dendrite formation in solid-state lithium batteries (SSLBs).

What is the ASR of a Li/Garnet interfacial impedance?

The ASR calculated from the stripping/plating test, based on Ohm's law, is $110 \, \Omega \cdot \text{cm}^2$, close to the total garnet ASR measured by EIS ($\sim 108 \, \Omega \cdot \text{cm}^2$), which indicates the effective removal of the Li/garnet interfacial impedance.

What is Garnet electrolyte surface and lithiated alumina interface?

Interaction with the garnet electrolyte surface and the lithiated-alumina interface allows effective lithium cell with lithium metal anode, garnet electrolyte, and stable solid-electrolyte interphase (SEI) formation, and poor cycling performance. Solid-state electrolytes (SSE) are the enabling material for the successful development

What are the challenges faced by Garnet electrolytes?

One of the major challenges is the large interfacial resistance between garnet electrolyte and electrode materials due to its rigid ceramic nature. Heating or even melting Li metal for its integration with garnet electrolytes has been reported [28].

Do Interfacial failure mechanisms exist in Garnet SSE systems with high-capacity anodes?

However, critical interface challenges still persist in practical implementations. This review systematically examines interfacial failure mechanisms in garnet SSE systems with high-capacity anodes (Si, metallic Li) through combined mechanical-electrochemical perspectives.
